**Analysis of Advanced Direct-Injection Diesel Engine Development Strategies Oct 22 2020** The methodology of achieving a high power density (HPD, or brake mean effective pressure) direct-injection Diesel engine has been studied, which is directed to using high fuel/air ratio, high-speed and ceramic engine components. Among the main thrust to achieve these engine changes for an advanced Diesel engine is the design of a high injection pressure (HIP) fuel system. During the course of the present study, two Cummins 903 engines mated with a Rutgers-built HIP were employed to investigate the engine response to HIP and in-cylinder processes by using the Rutgers high-speed infrared (IR) spectral digital imaging system. Five separate technical publications were prepared to report results obtained from the study. The main findings include: The HIP system permits engine operation at an air/fuel ratio of as rich as 18 to 1 with smoke emission not worse than with the conventional mechanical (low pressure) injection system; A high injection pressure improves HPD of a Diesel engine; A HIP unit promotes the (invisible) preflame reactions during the ignition delay period; The formation of the very first flame kernel is significantly affected by a cetane improver (fuel additive); The new three-color method developed in the present study was used to determine simultaneous distributions of temperature, soot and water vapor in the engine cylinder; and more. The techniques developed on the present ARO-sponsorship were employed in other engine studies and carried out under the sponsorship of industrial members and other U.S. governmental components.

**Piston and Ring Assembly Friction Studies in Cummins 903 Engine  
Jan 17 2023** Piston and ring assembly friction has been measured in a single cylinder Cummins 903 diesel. The engine was motored and fired, cooled and uncooled. For uncooled operation, plasma sprayed chromium oxide ring and liner coatings were employed with a synthetic lubricant. The Instantaneous IMEP and Fixed Sleeve methods were used for the friction measurement on a crank angle by a crank angle basis, with a cycle average of about 1.5 to 4 psi fmep. Considerable effort was expended in developing the measurement techniques, with a major effort on the Instantaneous IMEP method. In a parallel effort a bench type, heated, piston ring and liner wear simulator was developed. This permitted rapid screening of promising candidate materials for uncooled engine tests. The plasma sprayed chromium oxide coatings were found to be best.

**Study of Very High Pressure Fuel-Injection for High-BMEP DI-Diesel Engine May 09 2022** In order to help design a high-power-density (HPD) low-heat-rejection (LHR) high-injection-fuel (HIP) direct-injection compression-ignition engine (DI-CI, two main methods were employed: (1) engine performance analysis; and (2) in-cylinder imaging. In the performance analysis, a Cummins 903 engine was used. The range of air/fuel ratio studied was from 18-1 to over 35-1, the injection pressure investigated was as high as 30,625 psi (210 Mpa) under varied intake air temperature over 150 deg C. In the in-cylinder imaging, a separate optical single-cylinder Cummins 903 engine was used. A high-speed four-color IR digital imaging system was greatly improved during this contract period. New spectrometric methods were developed to simultaneously determine the distributions of temperature, water vapor and soot concentrations. In addition, a new data analysis and presentation method has been developed. The performance analysis results are reported in two parts: a preliminary report as included in Appendix-I and an additional set of results (Appendix-III). Some of the in-cylinder imaging results, which are now being captured by the improved 515 after incorporating with new electronic packages (designed and fabricated in our laboratory), are included with discussions.
